### Analysis Of Reinforced Concrete Structures

The reinforced concrete structure used most widely in engineering practice is mainly composed of one-dimensional members, of which the internal forces on the section are singly axial force, bending moment, shear force, or torque and the composition of them. Even the two- and three-dimensional structures are entirely or partly simplified and equivalent to a one-dimensional member.

Several reinforced concrete (RC) structures fail via concrete crushing in compressed zones. This is the case, for instance, of over-reinforced concrete beams, like in the four point bending tested by Mansur et al. [1]. When fiber-reinforced, the post-peak behaviour of such members is remarkably more ductile than that observed in beams having the same geometry, the same steel rebars, and the same bearing capacities, but made of normal concrete (NC) without fiber.

The fundamental propositions on which the mechanics of reinforced concrete is based are as follows: 1. The internal forces, such as bending moments, shear forces, and normal and shear stresses, at any section of a member are in equilibrium with the effects of the external loads at that section. 2.
